The HIV-1 regulatory protein Vpr (96 amino acid residues) is incorporated into the virus particle through a mechanism involving its interaction with the C-terminal portion of Gag. Vpr potentiates virus replication by interrupting cell division in the G2 phase and participates in the nuclear transport of proviral DNA. The domain encompassing the 40 C-terminal residues of Vpr was shown to be involved in cell cycle arrest and binding of nucleocapsid protein NCp7, and suggested to promote nuclear provirus transfer. Accordingly, we show here that the synthetic 52-96 but not 1-51 sequences of Vpr interact with HIV-1 RNA. Based on these results, the structure of (52-96)Vpr was analysed by two-dimensional 1H-NMR in aqueous TFE (30%) solution and refined by restrained molecular dynamics. The structure is characterized by a long (53-78) amphipathic alpha-helix, followed by a less defined (79-96) C-terminal domain. The Leu60 and Leu67

Record Date Created: 19990301

side-chains are located on the hydrophobic side of the helix, suggesting their involvement in Vpr dimerization through a leucine zipper-type mechanism. Accordingly, their replacement by Ala eliminates Vpr dimerization in the two hybrid systems, while mutations of Ile74 and Ile81 have no effect. This was confirmed by gel filtration measurements and circular dichroism, which also showed that the alpha-helix still exists in (52-96) Vpr and its Ala60, Ala67 mutant in the presence and absence of TFE. Based on these results, a model of the coiled-coil Vpr dimer has been described, and its biological relevance as well as that of the structural characteristics of the 52-96 domain for the different functions of Vpr, including HIV-1 RNA binding, are discussed. dividing cells. We have characterized by 2D NMR the solution conformations H(F/S)RIG sequence motifs (residues 71-75 and 78-82 of HIV-1 Vpr) that Vpr71-96, in which the sequence motifs were located at the N-terminus, were chemical shifts. Thus, the HFRIG and HSRIG motifs adopt alpha-helical and cause cell membrane permeabilization and death in yeast and mammalian collowed by a less ordered region. On the other hand, peptides Vpr71-82 and were studied in aqueous trifluoroethanol. Peptide Vpr59-86 (residues 59-86 Vpr, one of the accessory gene products encoded by HIV-1, is a 96-residue of Vpr) formed an alpha-helix encompassing residues 60-77, with a kink in (FFRIG) participated in the well-defined alpha-helical domain whereas the second (HSRIG) lay outside the helical domain and formed a reverse turn largely unstructured under similar conditions, as judged by their C(alpha)H of bioactive synthetic peptide fragments of Vpr encompassing a pair of pre-integration complex to the nucleus and inducing growth arrest of are largely unstructured in isolation. The implications of these findings turn structures, respectively, when preceded by a helical structure, but he vicinity of residue 62. The first of the repeated sequence motifs protein with a number of functions, including targeting of the viral cells. Due to limited solubility of the peptides in water, their structures for interpretation of the structure-function relationships of synthetic peptides containing these motifs are discussed.

Vpr, one of the accessory gene products of the human immunodeficiency Vpr were synthesized and their structures determined by circular dichroism functions as a transcriptional activator of HIV and heterologous promoters. Vpr remains poorly understood. To gain insight into the structure-function virus-1 (HIV-1) genome, exhibits diverse biological characteristics. Vpr relationship of Vpr, peptides corresponding to putative helical regions of findings are consistent with the results from mutational studies of Vpr and (CD) spectroscopy. The CD studies confirmed the predicted helical alpha-helix core structure reminiscent of a helix-loop-helix motif. These structures of these peptides. Based on the data, a hypothetical model for information available on the biological aspects of Vpr, the structure of the structure of Vpr was proposed which displays an anti-parallel crucial role in the infection of macrophages. Despite the wealth of provide a plausible structural basis to further investigate the multiple It is capable of arresting cells in cell cycle progression and plays a functions of Vpr as a viral protein

Human immunodeficiency virus (HIV) Vpr contributes to nuclear import of (1)H NMR spectroscopy allows the signal assignment of N- and C-terminal that circulating forms of Vpr observed in HIV-infected patients may exert other HIV-1 proteins and appears to be independent of cellular receptors. the extracellular medium by cells in a process that occurs independent of the viral pre-integration complex and induces G(2) cell cycle arrest. We dimers in aqueous trifluorethanol, whereas oligomers exist in pure water. Following cellular uptake, Vpr is efficiently imported into the nucleus of acids. In biological studies we found that Vpr is efficiently taken up from unstructured at neutral pH, whereas under acidic conditions or upon folding of Vpr may require structure-stabilizing interacting factors such transduced cells. Extracellular addition of Vpr induces G(2) cell cycle as previously described interacting cellular and viral proteins or nucleic describe the production of synthetic Vpr that permitted the first studies addition of trifluorethanol it adopts alpha-helical structures. Vpr forms amino acid residues; however, the central section of the molecule is obscured by self-association. These findings suggest that the in vivo arrest in dividing cells. Together, these findings raise the possibility on the structure and folding of the full-length protein. Vpr is biological effects on a broad range of host target cells.
